Parkinsonism as presenting symptom of primary hyperparathyroidism: Improvement after surgery

Parkinsonismo como síntoma principal de hiperparatiroidismo: recuperación tras cirugía

Abstract

Introduction: Hypercalcemia can cause different neurological disorders, depending on the calcium level. We report an exceptional case of primary hyperparathyroidism presenting as neurological alteration and it has favourable outcome after parathyroidectomy. Case report: A 74-year-old woman presented with progressive cognitive deterioration and impaired motor function. The complementary tests showed hypercalcemia due to a parathyroid adenoma. Parathyroidectomy was performed with symptomatic improvement. Conclusion: Cognitive impairment of the elderly due to a parathyroid adenoma is underdiagnosed, behavioral changes and alterations of motor functions are attributed to age, dementia and frailty, representing a diagnostic challenge.

KEY WORDS: Parkinsonism. Primary hyperparathyroidism. Hypercalcemia

Resumen

Introducción: La hipercalcemia puede causar diferentes trastornos neurológicos, dependiendo de las concentraciones de calcio. Aportamos un caso excepcional de hiperparatiroidismo primario que se manifestó con deterioro neurológico rápidamente evolutivo y se resolvió mediante paratiroidectomía. Caso clínico: Mujer de 74 años que consultó por deterioro cognitivo progresivo y alteración de las funciones motoras. Las pruebas complementarias evidenciaron hipercalcemia debida a un adenoma paratiroideo. Se realizó paratiroidectomía, con mejora sintomática. Conclusión: El deterioro cognitivo del anciano por un adenoma paratiroideo está infradiagnosticado, pues los cambios de conducta y las alteraciones de las funciones motoras se atribuyen a la edad, la demencia y lafragilidad, suponiendo un reto diagnóstico.

Introduction

Clinical manifestations of primary hyperparathyroidism (PHPT) are associated with excess of circulating parathyroid hormone (PTH) and hypercalcemia. High calcium levels can cause different neurological disorders. We present an exceptional case of PHPT that had an onset with rapidly evolving Parkinsonism and was resolved after parathyroidectomy.

Clinical case

A 74-year-old woman with a history of hypertension, dyslipidemia, intrinsic asthma and hysterectomy, sought medical attention for progressive cognitive impairment with motor function alteration, partial disorientation, bradypsychia, and rapid onset gait abnormality, all of these symptoms suggestive of Parkinsonism.

Brain MRI (Fig. 1) revealed chronic small vessel ischemic lesions, index 10 Parkinsonism, not suggestive of progressive supranuclear palsy. Laboratory tests showed calcium 14 mg/dL, phosphorus 2.1 mg/dL, PTH 483 pg/mL, normal tumor markers and renal function without alterations. Cervical ultrasound (Fig. 2) reported an enlarged thyroid gland with bilateral nodules of up to 11 mm and, adjacent to the lower pole of the left thyroid lobe, a well-defined, hypoechoic and homogeneous nodule with a size of about 10 mm of probable parathyroid origin was observed.

Treatment was started with zoledronic acid and, after analytical parameters normalization, the patient showed symptom improvement, walking without support, with agile gait and without tremor, with recovery of her baseline state. An elective intervention was practiced, with a right thyroid nodule and a right inferior parathyroid adenoma being found. Hemithyroidectomy and parathyroidectomy were carried out, intraoperatively verifying a PTH decrease and performing histopathological examination of parathyroid tissue.

Pathological anatomy analysis reported a 3.27-g parathyroid adenoma and hemithyroid gland with colloid nodule. The patient is currently asymptomatic, with normal calcium and PTH.

Discussion

PHPT is an endocrine disorder that mainly affects postmenopausal women by altering the phosphocalcic metabolism. These patients usually present with nephrolithiasis, osteitis fibrosa cystica or recurrent renal lithiasis, all of them absent in our patient. Parkinsonism as a symptom of PHPT presentation is extremely rare, with very few cases described in the literature.

Calcium-PTH homeostasis alteration can be a risk factor or an aggravating factor for the development of Parkinsonism. Calcium is necessary for the regulation of neuromuscular membrane excitability and neurotransmitter release. Elevated calcium concentrations can influence on dopamine receptor structure and function, thereby interrupting neuronal signaling.

Global cognitive deterioration in the elderly due to a parathyroid adenoma is underdiagnosed. Behavioral changes and alterations in motor functions are usually attributed to age, dementia and frailty, thus entailing a diagnostic challenge. Therefore, these patients can benefit from medical-surgical treatment, as in the case of our patient, who exhibited a remarkable recovery of all cognitive and motor functions after hypercalcemia correction and parathyroidectomy.
Ethical responsibilities

Protection of people and animals. The authors declare that no experiments on humans or animals have been conducted for this research.

Confidentiality of data. The authors declare to have followed the protocols of their work center on the publication of patient data.

Right to privacy and informed consent. The authors have obtained informed consent from the patients and/or subjects referred to in the article. This document is in possession of the corresponding author.
